

Digital Breadcrumbs & Dietary Diversity:  
Can mobile phone metadata predict food security  
outcomes among rural Haitian households?

Travis J. Lybbert (UC Davis)

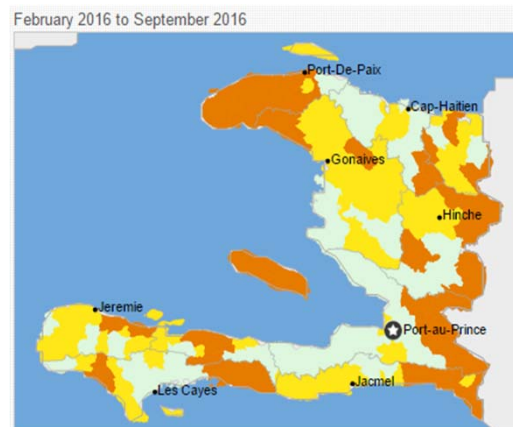

with Daniel Putman, Oscar Barriga Cabanillas and Joshua Blumenstock

ASSA Virtual  
4 January 2021

# A Serendipitous & Irresistible Research Opportunity

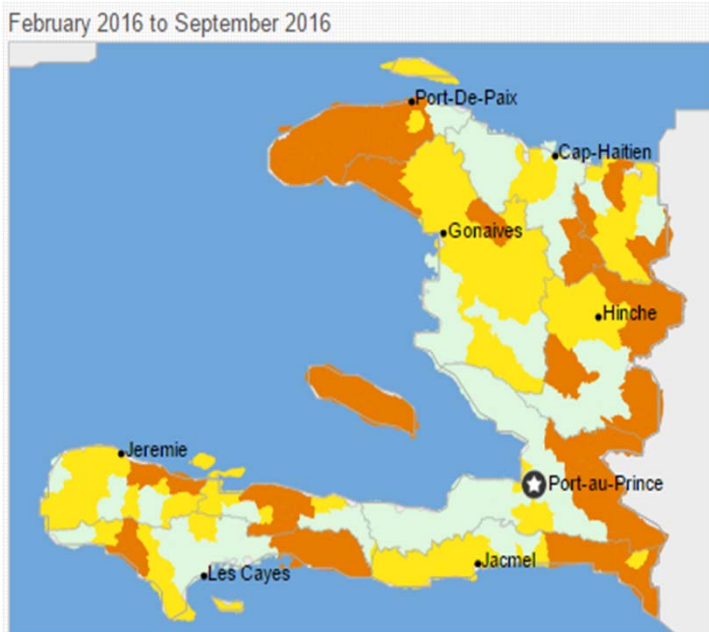

Can CDR-based wealth prediction methods (e.g., Blumenstock et al., 2015) be harnessed for CDR-based impact evaluation?

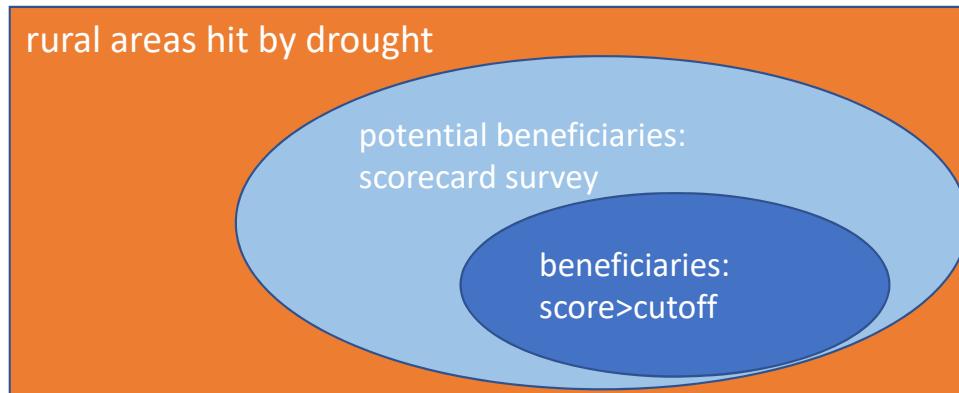

**Benchmark:** Conventional Regression Discontinuity (RD) evaluation of impact on food consumption using survey data

How closely can we replicate this estimated impact with a CDR-based evaluation that uses *predicted* food consumption outcomes?

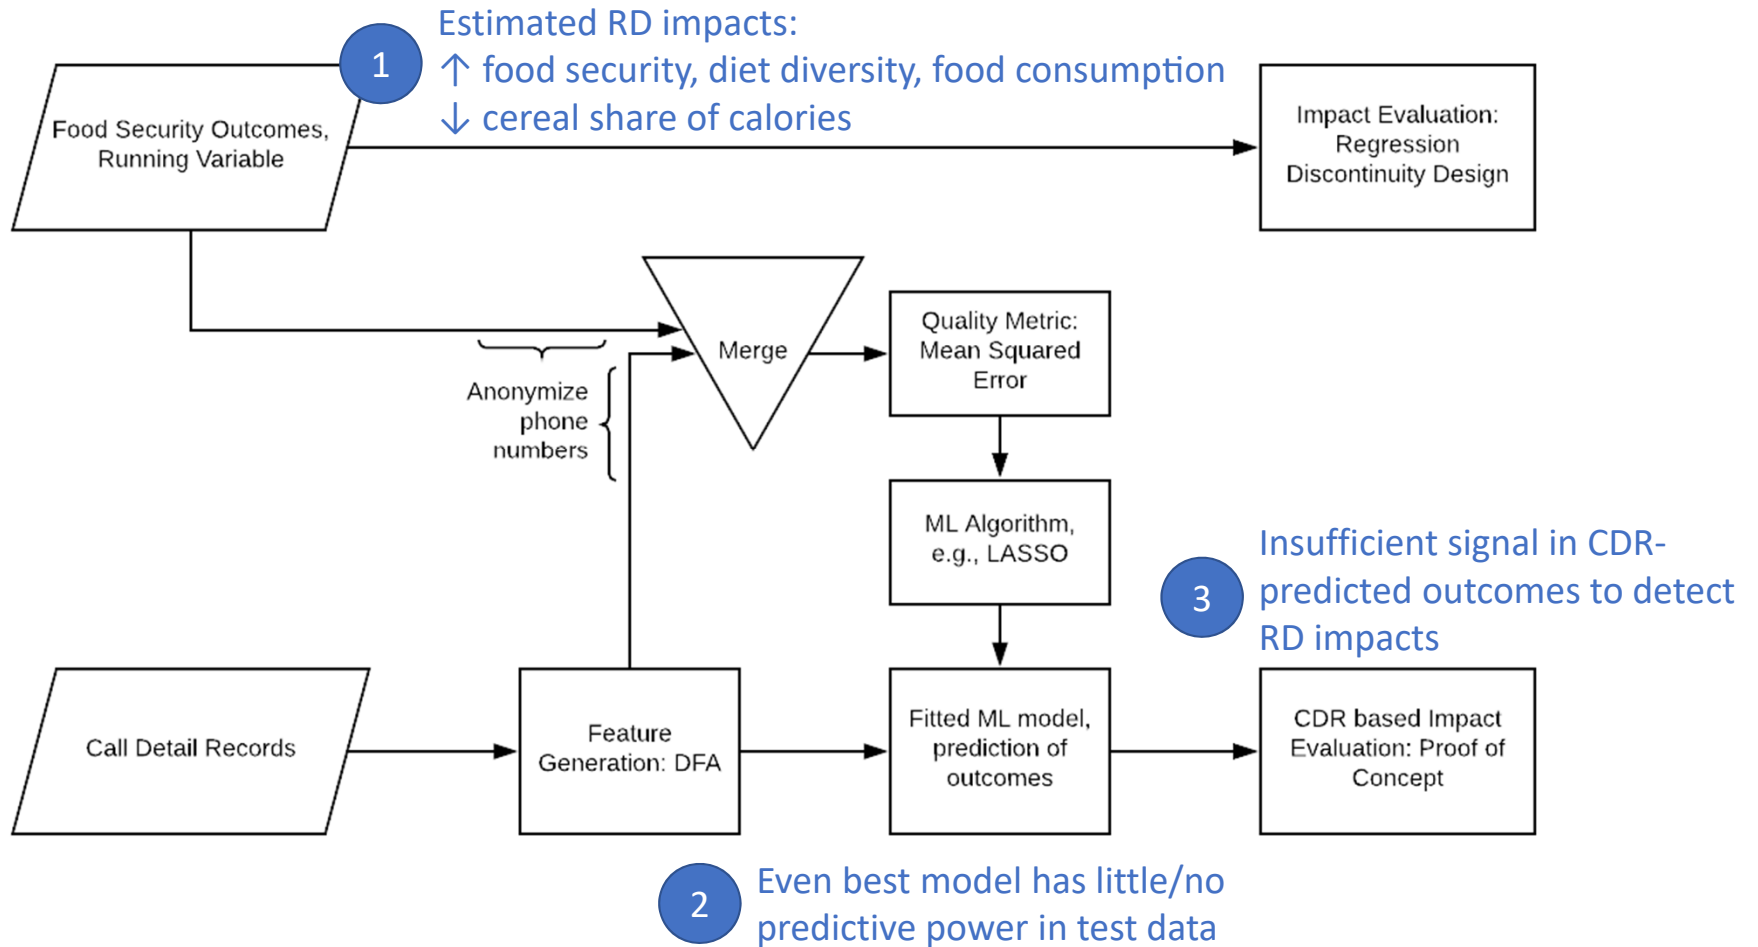

# WFP's 2016 (Unconditional) Cash Transfer

- In wake of 2014-15 drought, WFP launches emergency cash transfer (EMOP) targeting the hardest hit rural areas
  - Goal: 700,000 beneficiaries (140,000 households)
  - ~\$50/HH/month for 3 months
- *Mon Cash* distribution rolls out in 2016
  - New Digicel SIM cards distributed as needed
- Three tiered targeting

# Research Design & Preview of Results

# Data

## 1. WFP-led Scorecard

Sampling frame: 2<sup>nd</sup> targeting tier  
Normalized score: 3<sup>rd</sup> targeting tier

## 2. Researcher-led HH Surveys

Ground (in-person) survey

Phone survey

## 3. CDRs from full Digicel network

Phone numbers, time, duration, and towers connecting the calls for domestic and international calls, and SMS

Amount and time of transfers and top-up transactions

# Outcomes

- Food Security: WFP Indices

- Food Consumption Score (FCS)

- Number of days in past week specific food groups consumed

- Aggregated, weighted by nutritional value

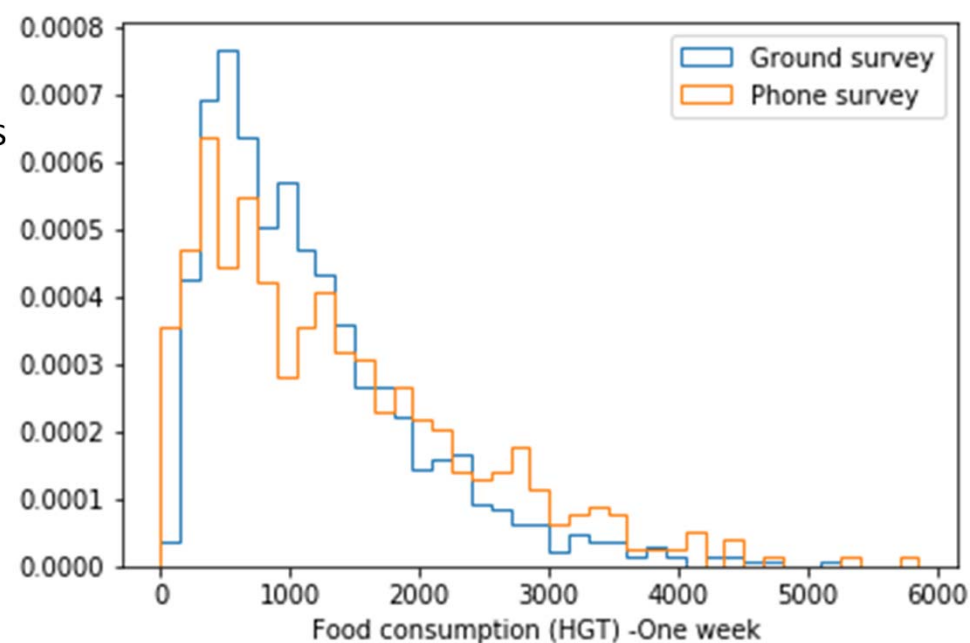

- Diet Diversity Score (DDS)

- Number of groups consumed over the past week

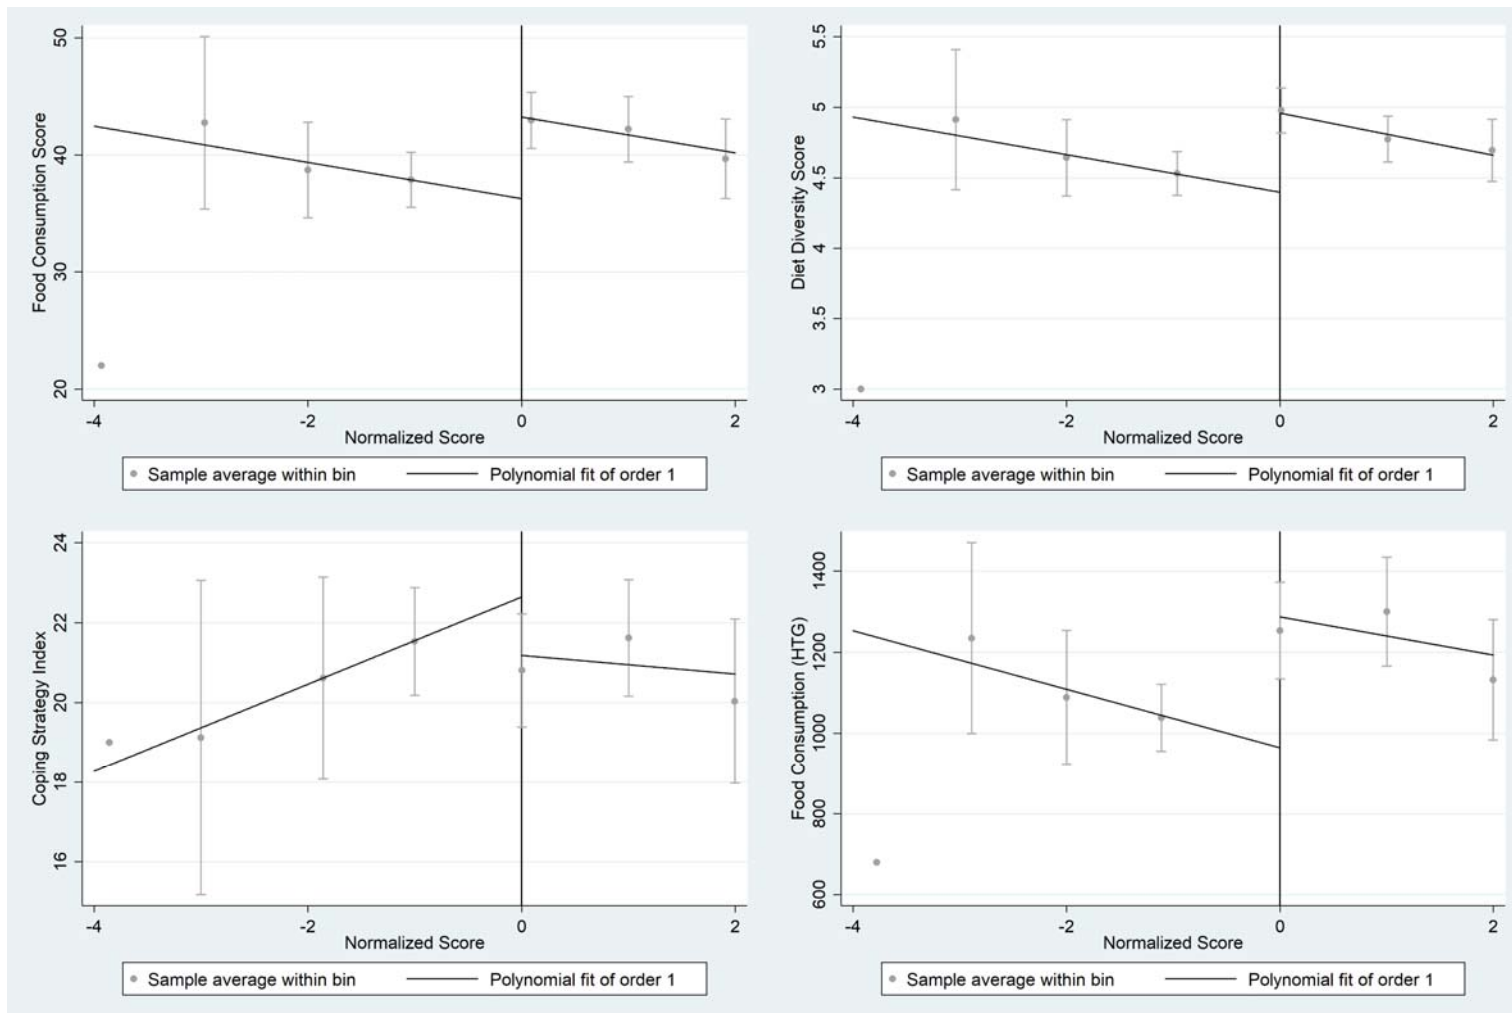

- Coping Strategies Index (CSI)

- Number of days in past week a certain strategy used, weighted by severity

- Food Consumption

# Conventional RD Results: EMOP worked

# Encouraging CDR-based predictions

- Blumenstock et al. 2015 use one year of CDRs to predict HH wealth and construct a high-resolution poverty map
- Decuyper et al. 2016 aggregate CDRs and national WFP food security survey to areas w/population 10,000-50,000

Figure 2. Quadratic combination of CDR variables against expenses on food. Correlation coefficient: 0.89.

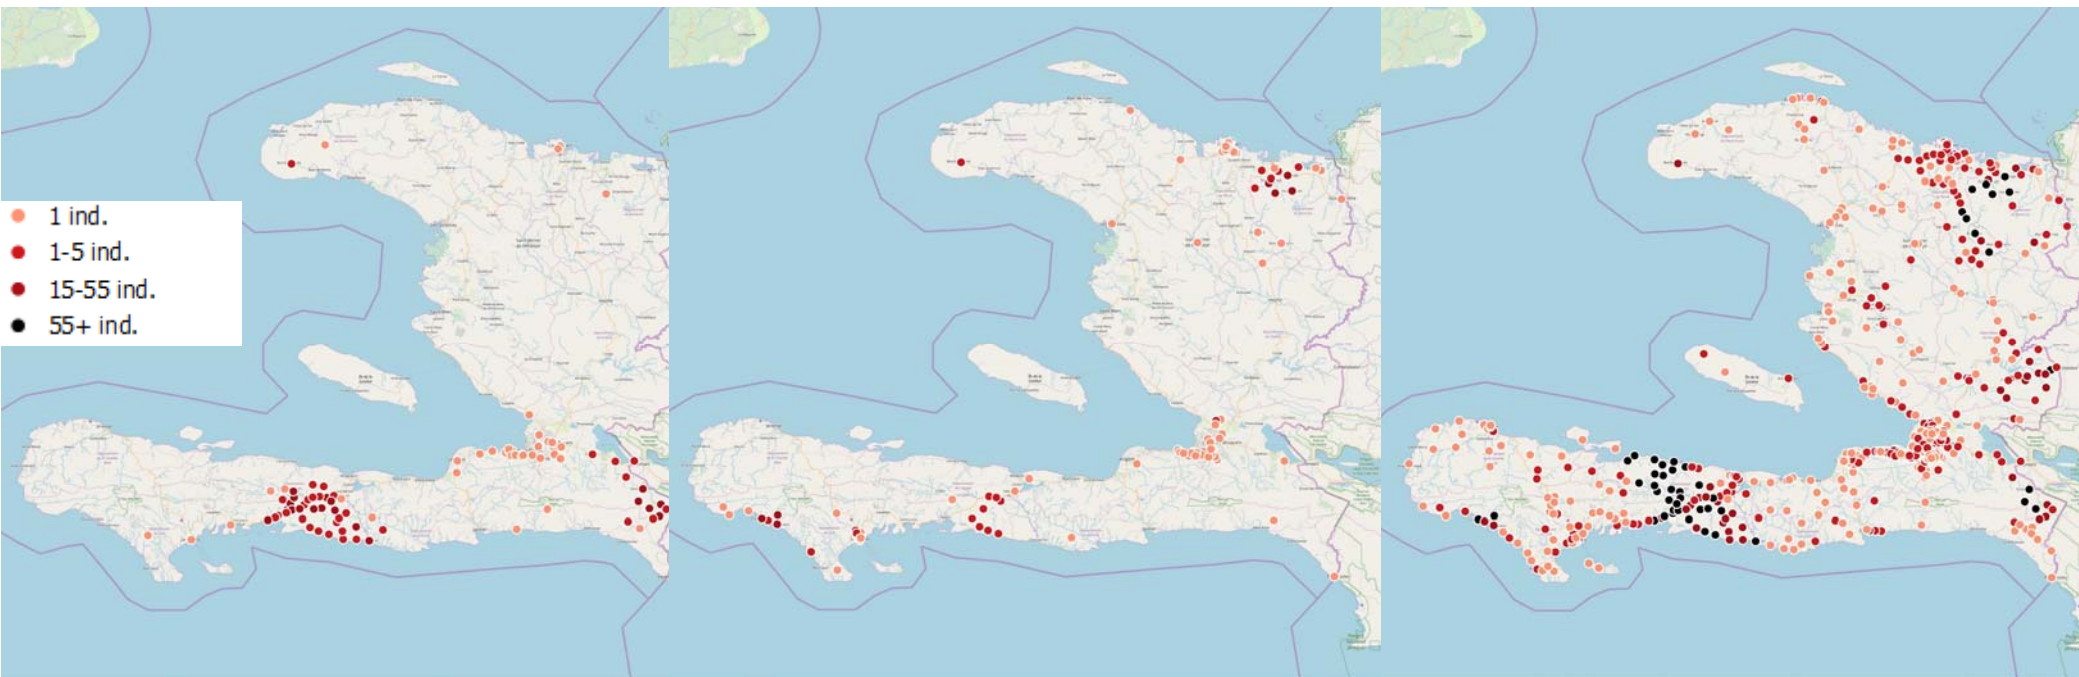

# Merged Survey & CDR data: Tower Locations of Survey Respondents

Ground survey

Phone survey

Scorecard survey

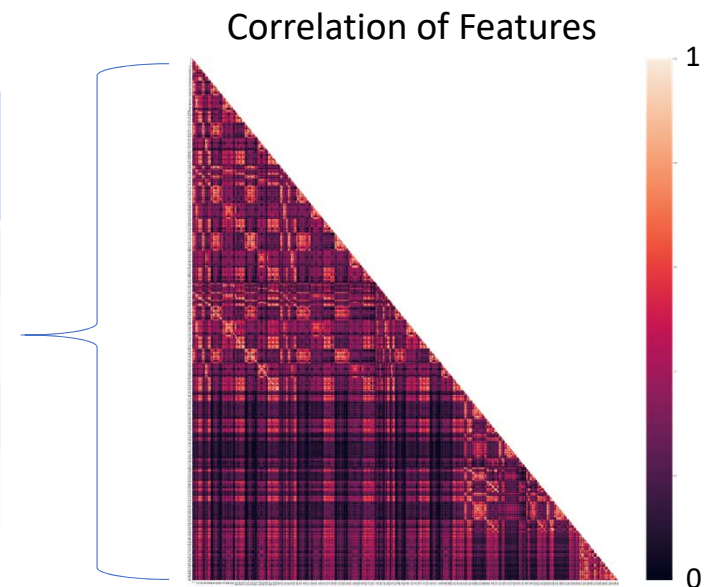

# Extracting Features from CDRs

- Define Feature Automata (DFA) extracts features to predict outcomes
- The full Digicel network used to extract ‘alter’ features in this DFA
- To synchronize features with consumption outcomes, we run the DFA over 4 different (pre-survey) time-windows
- We use Bandicoot (94 features) as alternative

Feature type	
Local network structure (ego)	
Call activity (ego)	
Global network structure	
Call activity (alter)	
Movement (alter)	
International communications (alter)	
SMS activity (alter)	
Movement (ego)	
International communications (ego)	
SMS activity (ego)	

Time window	Ground survey	Phone survey	Features
One-year	999	550	6,447
30-days	950	550	6,447
15-days	921	537	6,220
5-days	878	526	6,109

# Predictive Model: ~No feature-level predictive power

Individually, our features have very little predictive power in the test data

5-fold cross validation

~No change by time window

~No change by survey

Predicted outcome: Food Consumption  
Ground survey

One-year window

15-day window

30-day window

5-day window

# Predictive Model: Lasso doesn't do much better

- Feature selection using a 5-fold cross validation lasso model
- Slight improvement when features extracted from longer window (R-sq 0.015)
- Similarly poor prediction with alternate models
  - Ridge and elastic nets
  - Random forests
  - XGBoost
- Core problem: CDR features lack signal

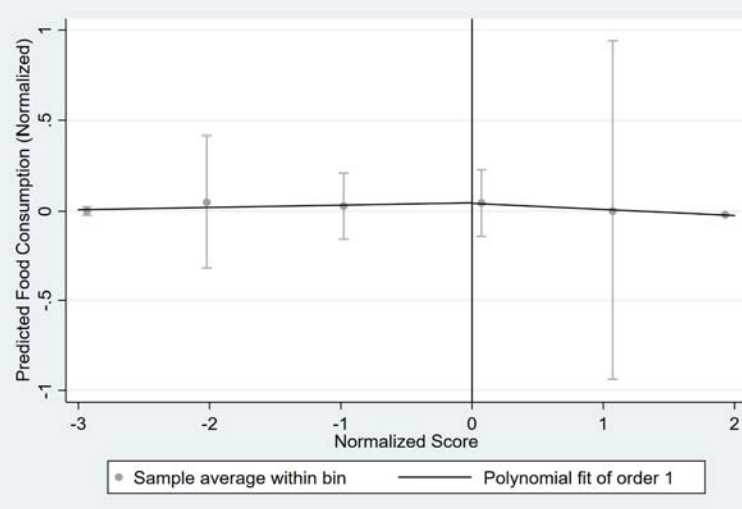

# CDR-based Impact Evaluation: RD with predicted food consumption

Obviously, with ~no predictive power, we can't replicate the conventional RD impact estimate

Survey Values

CDR-based Predicted Values

# Post-mortem: What went wrong?

## 1. Known sources of noise

CDR-related: Sharing phones or multiple phones per HH (e.g., new SIMs from EMOP)  
Hurricane Matthew (2 months prior to ground survey; ~70% of sample affected)

*Sample restrictions to avoid these known sources do not improve R-sq.*

## 2. Limited correlation of CDRs and food consumption

Predicting stocks (e.g., assets, wealth) easier than flows?

Do our CDR-based features predict anything?

Do transfers impact network activity?

*Probably. Not really. Yes.*

## 3. Effective programmatic targeting narrows range of HH wealth

Intentional focus on poor rural HHs limits variability of outcomes and CDRs?

*This is our primary suspect – still working on an empirical test.*

## 2. Limited correlation of CDRs and food consumption

Correlation=0.12

Can our CDR features predict more stable outcomes?

Wealth index?

Livestock?

...top-up recharges?

### 30-day window: Ground survey

Food consumption

Beneficiary

Livestock

nScore

Top-up

### 30-day window: Phone survey

Top-up

# Do EMOP transfers impact network activity at all?

- 1 week pre/post first EMOP transfer
- N=38,657 phone numbers
- Clear spike in network activity with apparent convergence to new higher level of usage and mobility

## 2. Effective programmatic targeting

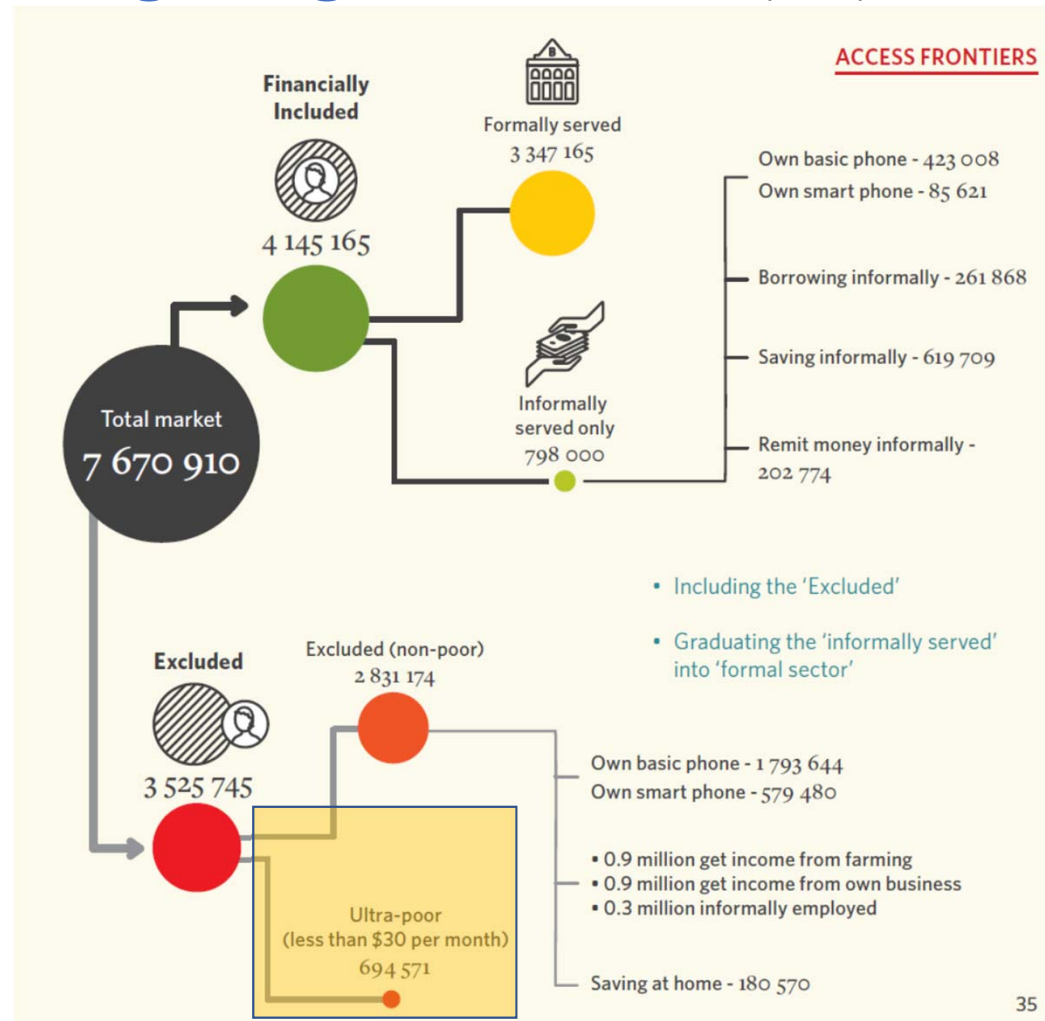

Explicit and effective targeting implied too narrow a range of outcomes and CDRs for CDR-based features to differentiate between HHs

Figure 2. Quadratic combination of CDR variables against expenses on food. Correlation coefficient: 0.89.

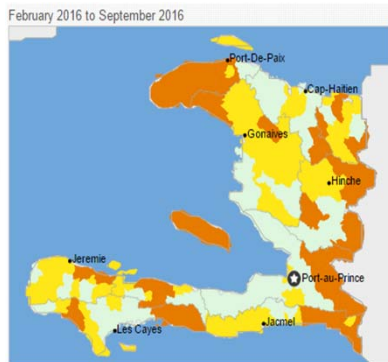

## 2. Effective programmatic targeting

Source: FinScope Report (2019)

- FinScope (USAID) 2018 data as a means of testing this suspicion
- Nationally representative (N=4,269)
- Detailed in-person survey
- ~Half are included in our CDR data
- Follow up survey with expanded informed consent underway
- Will allow us to test predictive power of CDR-based features across nationally-representative sample
- How much predictive power do we lose as we narrowly focus on the poor?

# Final Thoughts

Can CDR-based wealth prediction methods be harnessed for CDR-based impact evaluation?

- Not in this context, which seemed ideal in some ways
- If targeting undermines this test, then perhaps there is fundamental tension lurking between these methods
- Impact evaluation hinges on good counterfactuals
- Sharp focus on treated and comparable counterfactual units helps identification but hurts CDR-based prediction
- Better suited for interventions with coarser units of E(impact)?
  - Investments in irrigation or transportation infrastructure
  - Changes in local institutions or incentives
  - Local economy spillovers
- Lingering (untested) limitations on temporal resolution of CDR-based prediction?
